ABSTRACT

Key words: galaxies: high-redshift - galaxies: star formation - line: formation

1 INTRODUCTION

Due to the resonant nature of the Lyman alpha line, gas kinematics play an important role in the shape of this line. In particular we study the case in which this gas is spherically symmetric and its rotating.

2 IMPLEMENTATION OF BULK GAS ROTATION

We implement into CLARA the simplest model whereby a sphere rotates with homogeneous angular velocity. We define a cartesian coordinate system with its origin at the center of the sphere and the rotation axis to be the z -axis, the components in the bulk velocity field, $\vec{v} = v_x\hat{i} + v_y\hat{j} + v_z\hat{k}$, in the gas can be written as

$$v_x = -\frac{y}{R}V_{\max}, \quad (1a)$$

$$v_y = \frac{x}{R}V_{\max}, \quad (1b)$$

$$v_z = 0, \quad (1c)$$

where R is the radius of the sphere and V_{\max} is the linear velocity at the sphere's surface. The minus sign in the x -component of the velocity is due to the direction of rotation, in this case we assume that the angular velocity vector goes in the \hat{k} direction.

3 GRID OF SIMULATED MODELS

We compute the emergent Lyman- α line for several models with different values for the maximal rotational velocity, hydrogen optical depth, dust optical depth and initial distributions of the photons with respect to the gas. There are in total 60 models with the input parameters summarized in Table 1.

Additionally in the postprocessing process we will take

Velocity (km s ⁻¹)	V_{\max}	0, 50, 100, 200, 300
Hydrogen Optical Depth	τ_H	$10^5, 10^6, 10^7$
Dust Optical Depth	τ_A	XXX
Photons Distributions		Central, Homogeneous

Table 1. Values for the varying input parameters in CLARA. Taking into account all the possible combinations for these models

Figure 2. Spectra for different observers. Model: $V = 300 \text{ km/s}$, Optical Depth $\tau = 10^7$ and Central Distribution without dust.

into account different observer positions with respect to the cloud rotation axis.

Now if we take into account the position of the observer and compute this for different angles of observation θ the outgoing spectra is modified as is shown in Figure 2. The main feature here is that as the angle increases the line height decreases. It means that an observer in the poles will observe a higher double peak than an observer in the equator. We will understand this in more detail when we present the results of the escape fraction in section 4.3.

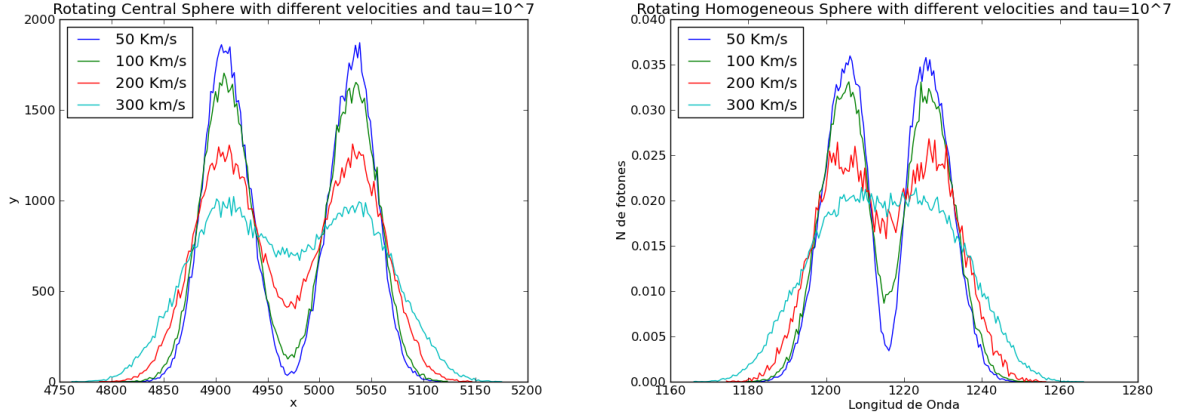

Figure 1. Shape of the Lyman alpha line for different velocities. The left panel shows the central distribution while the right panel shows the homogeneous distribution.

4 RESULTS

In the previous section we describe the models that we use to study the effect of rotation in the Lyman alpha line for this we saw the outgoing spectra including rotation. Now we show the main results that we obtain, in particular we pay special attention to the position of the maximums, the width of the line and the escape fraction in function of the rotational velocity and the angle of observation θ .

In Figure 3 the effect that rotation has in the spectra is shown, for both distributions central (Left) and homogeneous (right). This is a general case in the sense that is independent of the position of an external observer.

4.1 Maxima Positions

The maximums position gives information about the wavelength of the majority of the outgoing photons after they interact with the gas, in addition as a photon has more scatterings its wavelength would be larger than the initial which is 1216 Å. As we can see in Figure 4.1 the position of the maximums does not change with rotational velocity for the central distribution. On the other hand for the homogeneous distribution the maxima position X_m changes for $\text{Log}_{10}\tau = 5$, this is because at higher rotational velocities photons escape with less scatterings, for $v = 100 \frac{\text{km}}{\text{s}}$ the majority of the photons still escape with scatterings but for $v = 200 \frac{\text{km}}{\text{s}}$ the number of photons that escape with a few or any scatterings is higher, this is why the maxima change to the center of the spectra.

If we now study the effect of the optical depth τ in the maxima position X_m Figure 4.1, we found that as the optical depth increases (include reference of previous articles) the maxima position increases and this is a well known result, but when rotation is included the dependence is not linear.

4.2 Line Width

Another effect that the rotation of the gas produces is in the width of the Lyman alpha line. The width of the line provides

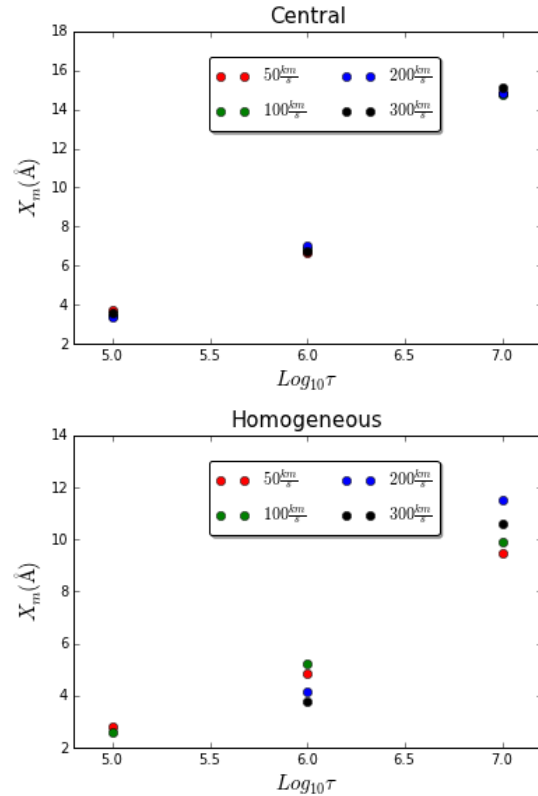

Figure 3. Position of the maxima in the outgoing spectra for different Optical Depths, (up) Central Distribution, (Down) Homogeneous Distribution.

information of how many photons escape with a particular wavelength, in the ideal case in which all the photons escape with the same wavelength the outgoing spectrum would be narrower. For all the models we study we found that as the rotational velocity increases the line width increases this is shown in Fig. [4].

We also found that the width for a particular model is not the same for different angles of observation in

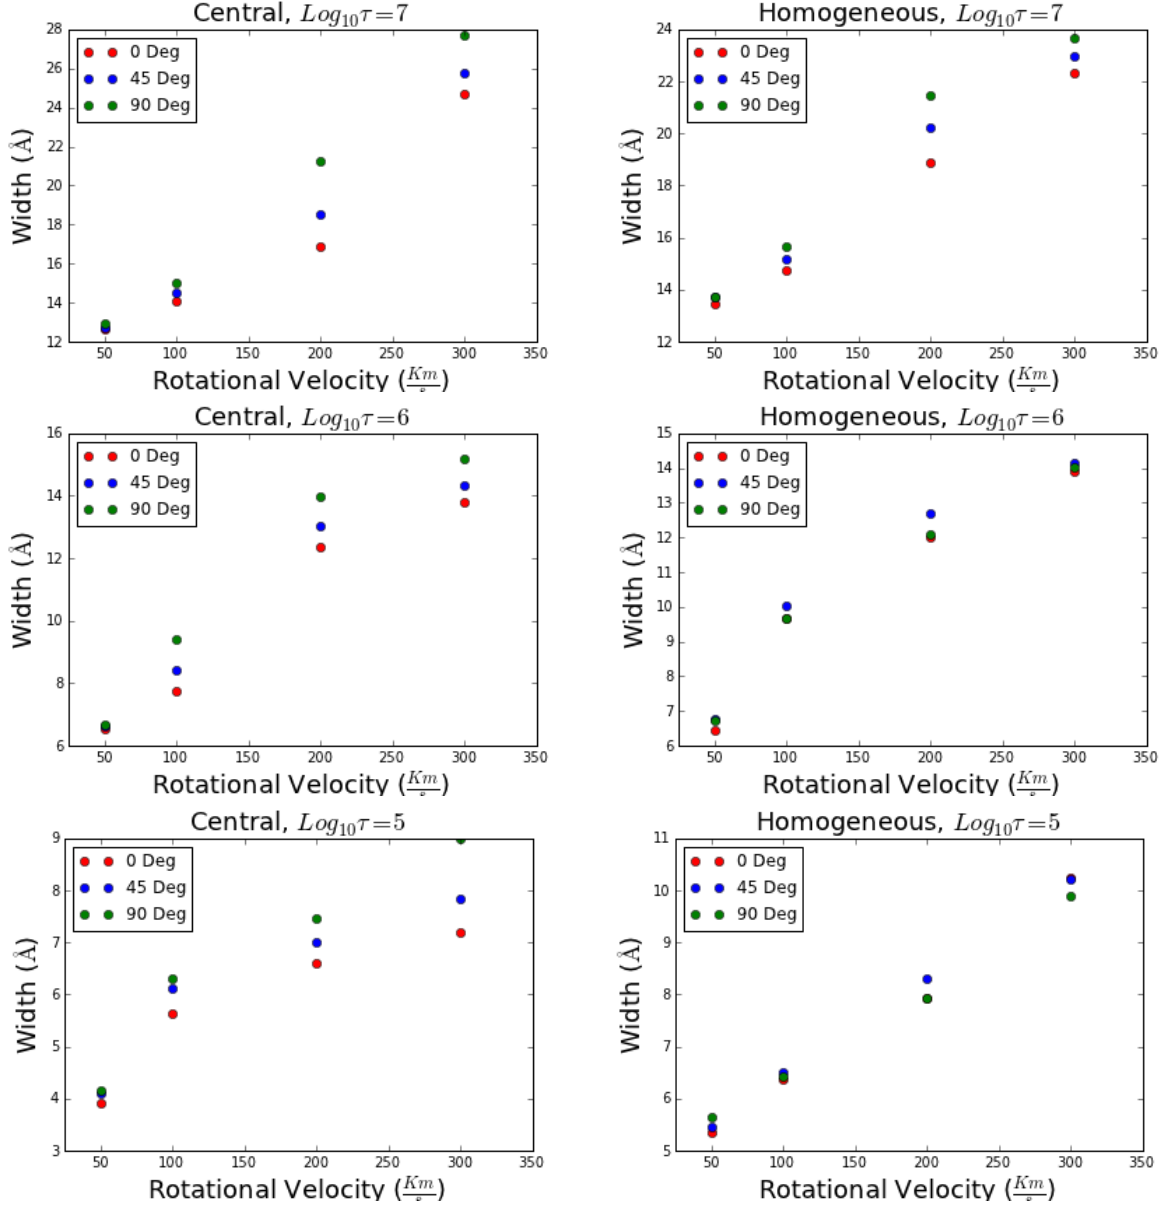

Figure 5. Width of the lyman-alpha line for all the models.

particular as the angle increase the width also increase, it means that as the angle increase the number of scatterings of the photons increase for this reason we see a broader line. Fig.[5]

4.3 Escape Fraction

The fraction of photons that escape from the cloud of gas and dust is defined as:

$$F_e = \frac{\Sigma_{NI} \vec{k} \cdot \vec{\sigma}}{\Sigma_{NF} \vec{k} \cdot \vec{\sigma}} \quad (2)$$

Where NI is the initial number of photons and NF is the final. This escape fraction is computed for all the

models which results are shown in Fig.[6]

When the distribution is homogeneous the effect of velocity in the escape fraction is clear while in the central model the effect is not notorious. The main effect is that the escape fraction increase as the velocity increase.

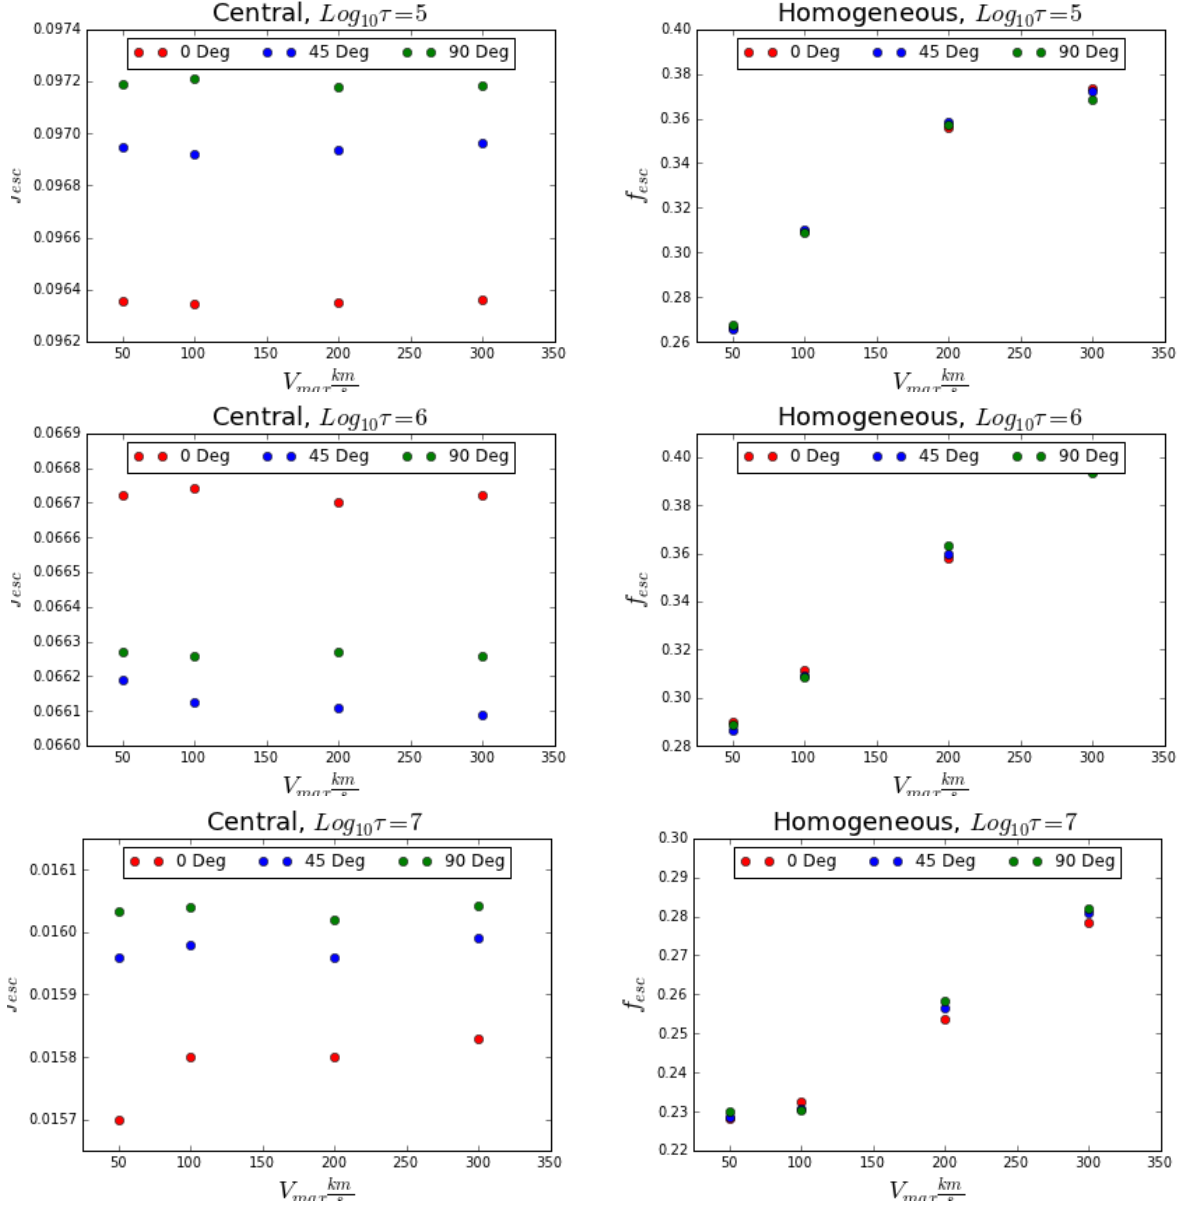

Figure 7. Escape fraction for all the models. Left panels show the central distribution, while right panels show the homogeneous distribution
